HEART DISEASE PREDICTION

Machine learning

Presented by PhilipBedit AJJ

INTRODUCTION

Machine learning is used across many spheres around the world. the health care industry is no exception.ML can play an essential role in predicting presence/absence heart diseases and more,
if predicted well in advance can provide important insight to doctor who can then adapt their diagnosis and treatment per patient basis.

OBJECTIVE

- we build a model for heart disease predict to whether the person who after with cartiopathy or not exploitation with different algorithms on the relevant dataset

PROBLEM STATEMENT

To automate the heart disease prediction process (real-time) based on customer detail provided while filling out online data . These details are Gender, age , FBS, cps, cholesterol, BP and others, To automate this process, they have provided a dataset to identify the whether a person who affect to heart disease or not

problem: binary problem
heart disease has to predict Yes or No

yes: affected
No: not affected

PROPOSED

Heart diseases prediction

proposed system is accuracy prediction of heart disease problem in health care application.

Easier to analyse the scalable of health care big data. Less time consumption with efficiency of data in heart disease.

High performance in data maintained of heart disease prediction.

algorithms- Random forest algorithms, Navie Bayes

Random forest

01

about

supervised machine learning algorithms, used for classification

02

what is RF

Random Forest is a classifier that contains a number of decision trees on various subsets of the given dataset and takes the average to improve the predictive accuracy of that dataset

03

why?

1.it reduces the risk of overfitting and required raining time.
2.it offers high level accuracy
3.run efficiently on large data set

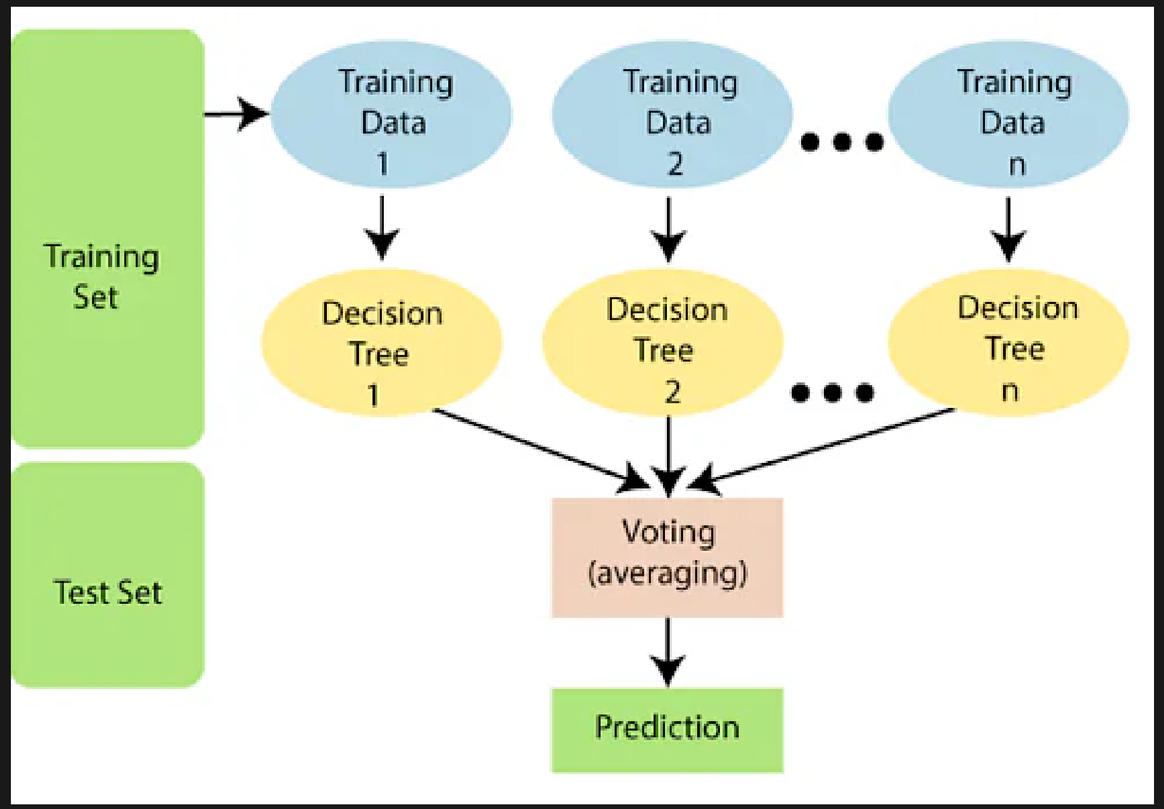

04

work

- Random Forest randomly selects observations, builds a decision tree and then the result is obtained based on majority voting. No formulas are required here.

working RF

works:

step 1: Select random samples from a given data or training set.

Step 2: This algorithm will construct a decision tree for every training data.

Step 3: Voting will take place by averaging the decision tree.

Step 4: Finally, select the most voted prediction result as the final prediction result.

Navie Bayies

01

about

supervised machine learning algorithms, based on Bayes theorem and used for classification problem

02

what is NB

- It is a probabilistic classifier, which means it predicts on the basis of the probability of an object.

03

why?

- Naïve Bayes Classifier is one of the simple and most effective Classification algorithms which helps in building the fast machine learning models that can make quick predictions.

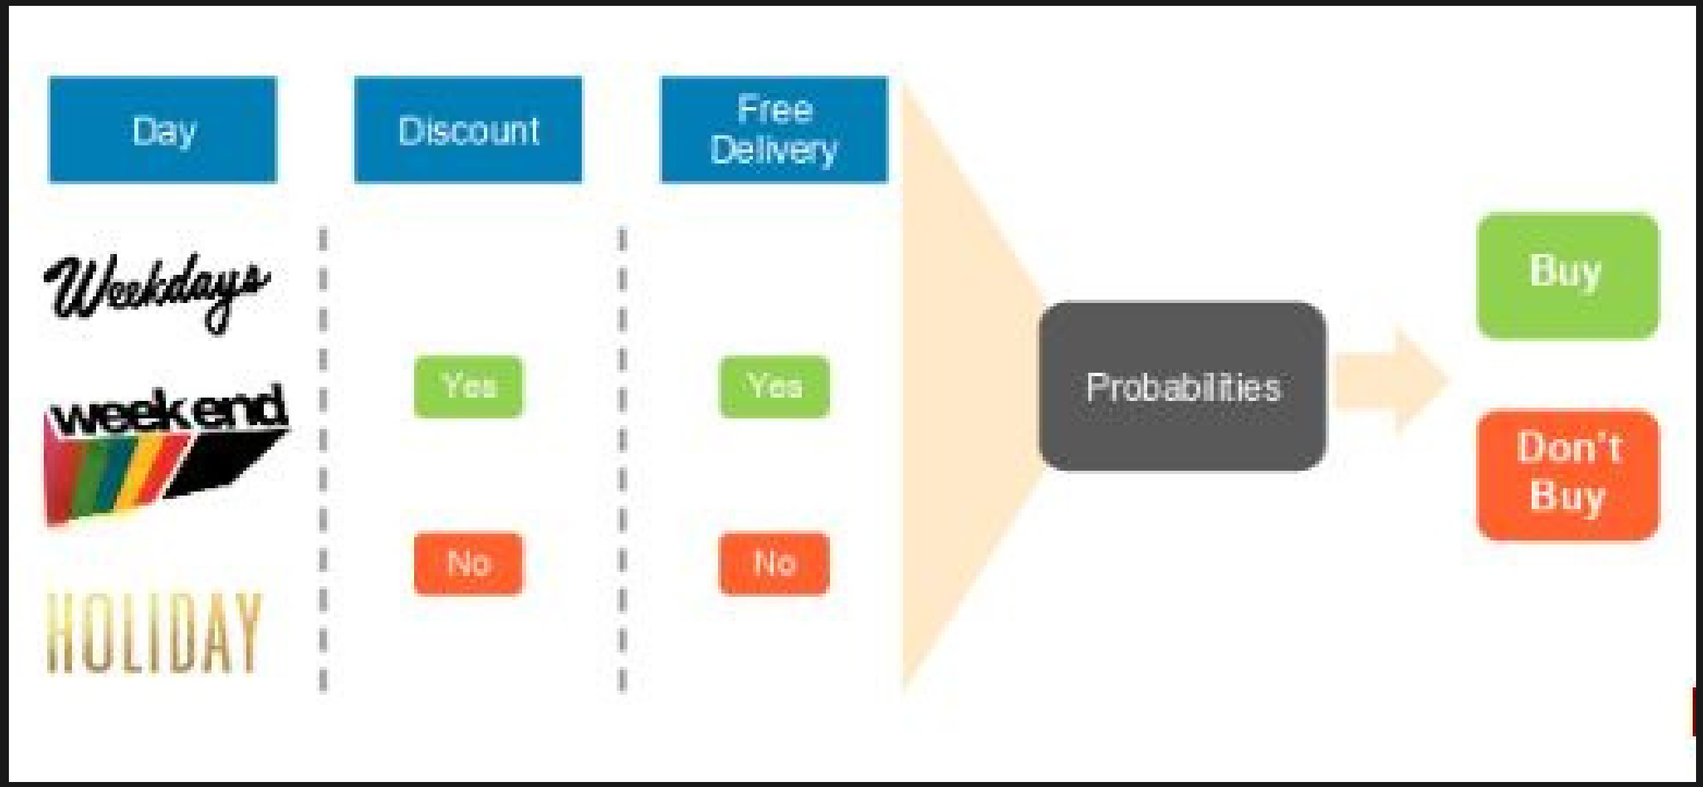

04

work

this algorithms works based on the bayies theormwhich is used to determine the probability of a hypothesis with prior knowledge. It depends on the conditional probability.

logistic Resgression

01

about

supervised machine learning algorithms,
used for classification or categorical

02

what is RF

Logistic regression predicts the output of a categorical dependent variable.Logistic regression is used to describe data and the relationship between one dependent variable and one or more independent variables. The independent variables can be nominal, ordinal, or of interval type.

03

why?

1.Logistic regression performs better when the data is linearly separable
2.it is easy to implement and train a model using logistic regression

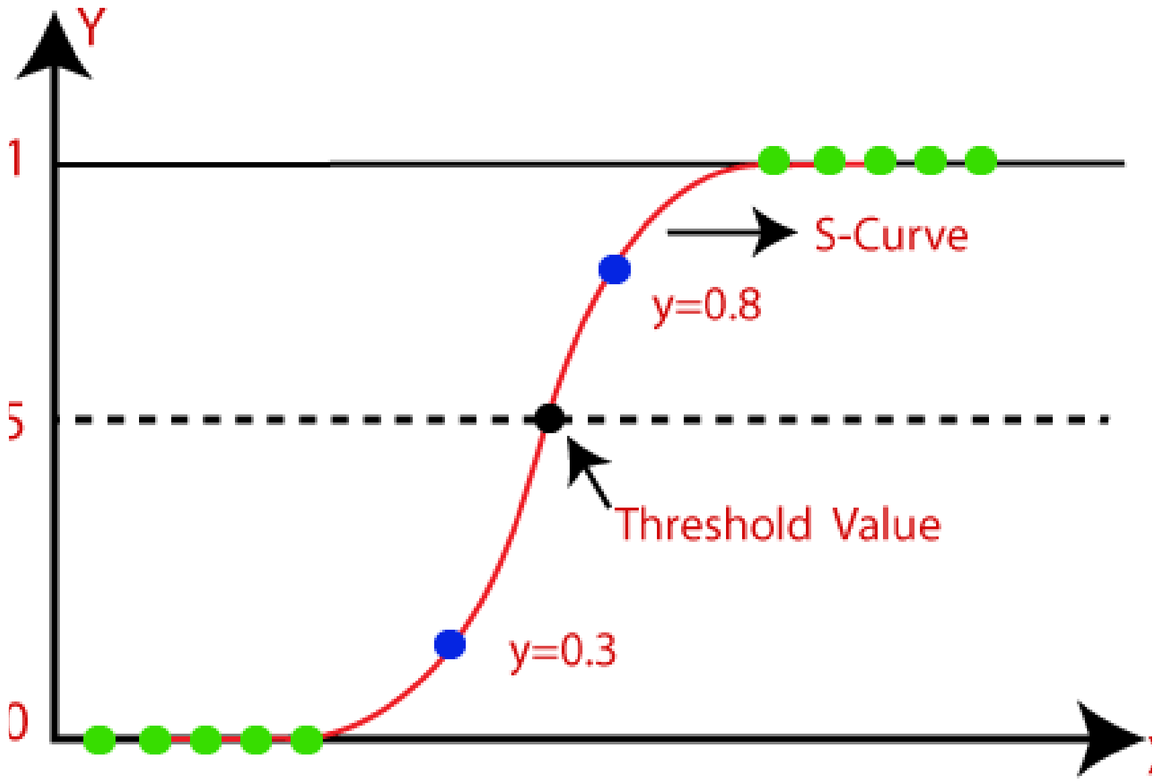

04

work

- “logistic regression” is derived from the concept of the logistic function that it uses. The logistic function is also known as the sigmoid function. The value of this logistic function lies between zero and one.

→

working LR

works:

- The sigmoid function is a mathematical function used to map the predicted values to probabilities.
- It maps any real value into another value within a range of 0 and 1.
- The value of the logistic regression must be between 0 and 1, which cannot go beyond this limit, so it forms a curve like the "S" form. The S-form curve is called the Sigmoid function or the logistic function.
- In logistic regression, we use the concept of the threshold value, which defines the probability of either 0 or 1. Such as values above the threshold value tends to 1, and a value below the threshold values tends to 0.
